Get Rhinestone Look, stay up-to-date with industry-recognized best practices and put your ideas to work. Explore the versatile Studio Ultimate, Rhinestone, Sequin and other best-selling software brands and discover the incredible new innovations for your designs. Presentations Speech impaired persons may have difficulty reading text off a screen in a PowerPoint presentation.

They may also have trouble viewing presentations at a distance. For both of these issues, there are a variety of solutions. The first is to use a free software alternative such as Keynote. The other is to use wireless speakers and external projectors.

**Projectors** A projector is a light source that projects an image on to a surface, such as a screen. They project images from sources such as LCD, CRT, and LCD TVs. Projectors can be used for presentations, training, and video conferencing. They can be used at home, in offices, or even at public places. Due to their use, a projector can create a brilliant picture in a small room, by being much more powerful than other display devices. The use of a projector also enables a speech impaired person to watch the screen from a distance, thus improving their ability to view a presentation. A small laser projection system is available for this purpose. **Wireless speaker** Wireless speakers are speakers that use radio waves, rather than a physical electrical cord, to deliver sound to a room. They include the newer Bluetooth technology. These speakers are easy to use and inexpensive. They are best for one or a few people, in small rooms. A wireless speaker can be placed within six to ten feet of the screen. This range is sufficient to create a good sound that can be heard by a speech impaired person. The speakers can be turned on and off. These

speakers have a standby time of five to ten hours on average. **Bluetooth technology** Bluetooth technology is a low-power wireless technology. It can link up to 10 devices to a system. It is typically used to make wireless connections between cell phones and devices such as computers, tablets, and portable media devices. It can also be used to connect computers and mobile devices with their owners. Using Bluetooth technology, speech impaired persons can use their cell phone as a speaker to deliver sound directly to their ears. This technology does not require any physical devices to be connected, it just requires a cell phone, Bluetooth enabled, a hands-free headset, or a wireless speaker. 82157476af
